Type 1 diabetes as well as multiple sclerosis are thought to be T cell mediated autoimmune diseases that involve a detrimental action of inflammatory cytokines and autoaggressive T lymphocytes. They still pose many unsolved puzzles, and the precise etiology as well as prevention have remained elusive. It is clear that genetic factors can predispose for developing diabetes, however, based on significant disease discordance found in monozygotic twins, additional environmental factors have to be postulated. Viruses are good candidates because they induce strong cellular and humoral immune responses, but no single etiologic agent has been

identified. Several animal models are presented which have been used to study the activation of naive autoreactive lymphocytes. It is shown that regulation of the autoaggressive process occurs prior to clinical diabetes and is mediated by a complete network of cytokines, as well as regulatory circuits/cells. The spreading of autoimmunity to self-antigens not involved in the initial phase of islet destruction is not necessarily detrimental and can carry benefits. Therapeutically, counter-regulation of aggressive responses has been demonstrated via various means in animal models preventing diabetes or rejection of transplanted islets.

The prevalence of diabetes is on the increase in the UK and worldwide, partly due to changes in lifestyle which predispose individuals to overweight and obesity. It is estimated that about 90% of the currently diagnosed adults have type 2 diabetes, and based on the World Health Organisation (WHO) report, about 422 million adults were living with diabetes in 2014 compared with 108 million in 1980; this condition caused about 1.5 million deaths in 2012. In the United States of America, it is estimated that about 30.3 million adults are living with diabetes, with a further 1.5 million new diabetes cases diagnosed every year, representing an increasing prevalence of this condition. Diabetes represents a

major public health challenge, despite advances in technology and the pharmaceutical industry. These problems may be in the form of acute or long-term complications. Therefore, in order to attenuate the problems of diabetes, management strategies usually include lifestyle changes such as increased physical activity and dietary interventions. Studies which evaluate the role of nutrition in the management of type 2 diabetes often involve human and animal models as these approaches enable us to have a broader and more in-depth understanding of the condition. In some cases, diabetes may co-exist with other conditions, such as stroke, and these may present unique challenges with regard to nutritional interventions. This Special Issue aims to evaluate the risk factors associated with type 2 diabetes and the role of the diet in the management of people with this condition. This evidence is drawn from both human and animal studies.
